

ABSTRACT OF THE DISCLOSURE

A technique is disclosed for selectively scanning or encoding a desired region of a document. The desired region is identified via scannable indicia on a control form.

5 The region may be outlined by a border preprinted on the form or traced by a user.

Preset selectable regions may be identified by codes or other textual descriptions on the form. The form is scanned and the instructions selected by the user are encoded. The

selected region is identified and scanned. Only the selected region is scanned, or a larger region is scanned and extraneous data not corresponding to the selected region is

10 eliminated from the resulting data set. The technique permits elimination of unwanted

portions of a document automatically, the reduction in scanned file size, and

straightforward handling of batch scanning tasks in which selected portions of

documents are to be scanned and processed.
